Independent verification of element 114

Monday, 19 April 2010 08:30 (15 minutes)

Production of numerous superheavy elements (SHE) in ⁴⁸Ca irradiations of actinide targets was reported by the Dubna Gas Filled Recoil Separator (DGFRS) group in past years [1]. Independent verification of these observations has been of paramount importance, but confirmation experiments failed to produce SHE in ⁴⁸Ca induced reactions. We report on the first successful independent verification of the production of element 114 in the reaction ⁴⁸Ca(²⁴²Pu,3-4n)^{287,286}114 at a center-of-target energy of 244 MeV. Two genetically correlated decay chains were observed during 8-day experiment at the Lawrence Berkeley National Laboratory's (LBNL) 88-Inch Cyclotron. Based on the observed decay properties these decay chains were attributed to decay of ²⁸⁷114 and ²⁸⁶114 produced in 3n and 4n channel, respectively. Implications of this observation on chemistry and physics of the heaviest elements will be discussed.
