Comparison of eight possible ⁹⁹-molybdenum production routes

Monday, 12 May 2014 10:30 (30 minutes)

The present paper addresses eight possible routes of producing ⁹⁹Mo, and discusses both yield and ⁹⁹Mo specific activities (SA) in the context of future anticipated worldwide demand. The dimensions of the targets are modelled by considering both the limits set by cooling and those by inside-target radiation attenuation characteristics. Energy deposition profiles are modelled by MCNP6, the reaction probabilities are taken from TALYS/TENDL and JANIS codes, and both are used in calculating produced ⁹⁹Mo.

The results suggest that U neutron-fission may remain one of the most relevant and efficient means of producing ⁹⁹Mo, but that new developments may surface, such as ADSR or AHR production modes. Accelerator-based ⁹⁹Mo production is discussed as asking for developments in both the cooling of targets and new concepts in post-EOB upgrading of ⁹⁹Mo SA, and/or new concepts for ⁹⁹Mo/^{99m}Tc-generators, the latter possibly in both volumes (mass) and ⁹⁹Mo capacities.

Primary author: Prof. WOLTERBEEK, Bert (Delft University of Technology)

Co-authors: Dr WINKELMAN, August (Delft University of Technology); Dr LATHOUWERS, Danny (Delft University of Technology); Dr WOLS, Frank (Delft University of Technology); Dr KLOOSTERMAN, Jan-Leen (Delft University of Technology); Dr FRIMA, Lodewijk (Delft University of Technology); Dr ROHDE, Martin (Delft University of Technology)

Presenter: Prof. WOLTERBEEK, Bert (Delft University of Technology)

Session Classification: Plenary session 2

Track Classification: Production and Application of Radionuclides
