## Long term immobilization of Cs-137 by transformation of titanium ferrocyanide to lithium titanate

Monday, May 12, 2014 5:15 PM (1h 30m)

Radioactive waste contains a variety of radionuclides and arises in a variety of physical and chemical forms. In Poland, the amount of activity and waste volume of liquid wastes are relatively small, mostly from operation of research reactor. Despite of the low level radioactivity involved, there are many significant hazards that could arise as a result of inadequate management. Treatment of liquid wastes is needed to produce a waste product suitable for long term storage and disposal. Our idea of immobilization of the  $^{137}\text{Cs}$  radionuclide in the matrix of  $\text{TiO}_2$  is based on the initial sorption of  $^{137}\text{Cs}$  on titanium ferrocyanide (TCF) and then converting TCF to the  $\text{TiO}_2$ aq by hydroxide solution and calcination of the product to ceramic.

We showed that the TCF is a very effective sorbent for  $^{137}\text{Cs}$ . In the column experiments we did not observed any breakthrough of the column after passing 10000 bed volumes of the saline solution spiked with  $^{137}\text{Cs}$ . After adsorption of the  $^{137}\text{Cs}$  on TCF hydroxide solutions were passed through a column and degree of transformation of TCF to  $\text{TiO}_2$  and leakage from the column was examined. Hydroxides used were as follows :  $\text{LiOH}$ ,  $\text{NaOH}$ ,  $\text{KOH}$ , and  $(\text{CH}_3)_4\text{NOH}$ .

The obtained results indicate that all hydroxides studied convert, in 100 percent, the black TCF to the white  $\text{TiO}_2$ aq. However, when using  $\text{NaOH}$  and  $\text{KOH}$  competing influence of the cations  $\text{K}^+$  and  $\text{Na}^+$  causes leakage of  $^{137}\text{Cs}$  from formed  $\text{TiO}_2$  aq. Much better results have been obtained using tetraalkylammonium hydroxide and particularly lithium hydroxide. Competitions from bigger tetraalkylammonium cations and hydrated  $\text{Li}^+$  on sorption of small hydrated  $\text{Cs}^+$  cation is negligible. Collected samples of the titanium oxide with adsorbed  $^{137}\text{Cs}$  were next calcined at  $900^\circ\text{C}$  and the leaching of radionuclides has been studied.
